Transformations for variance stabilization

FORECASTING IN R

Rob J. Hyndman

Professor of Statistics at Monash
University

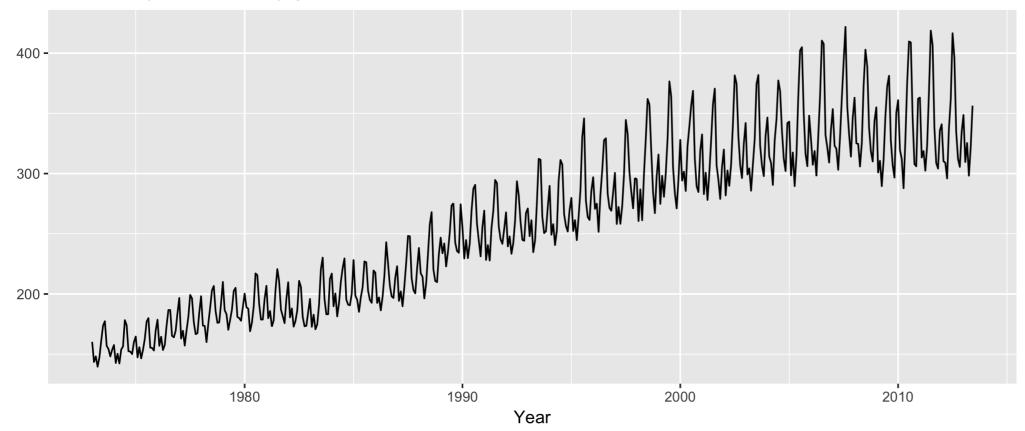

- If the data show increasing variation as the level of the series increases, then a **transformation** can be useful
- $y_1,...,y_n$: original observations, $w_1,...,w_n$: transformed observations

Square root	$w_t = \sqrt{y_t}$	↓
Cube root	$w_t=\sqrt[3]{y_t}$	Increasing
Logarithm	$w_t = \log(y_t)$	Strength
Inverse	$w_t=-1/y_t$	+

```
autoplot(usmelec) +
  xlab("Year") + ylab("") +
  ggtitle("US monthly net electricity generation")
```

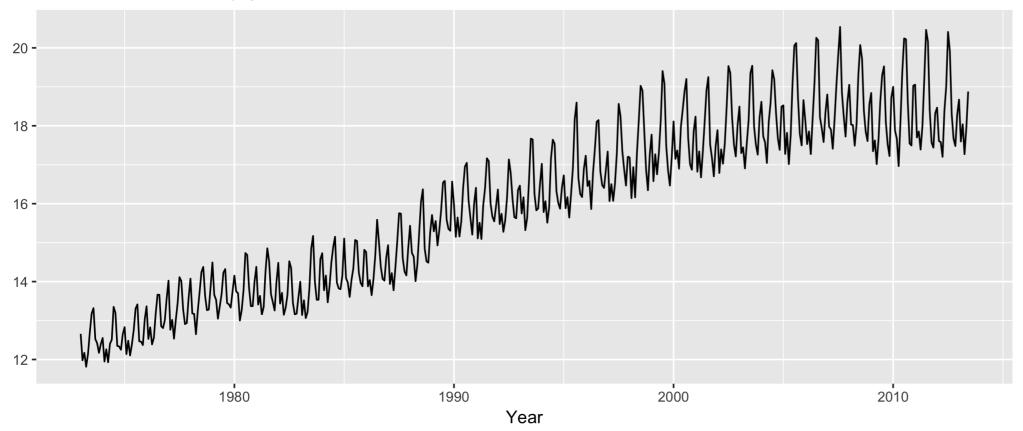

US monthly net electricity generation

```
autoplot(usmelec^0.5) +
  xlab("Year") + ylab("") +
  ggtitle("Square root electricity generation")
```

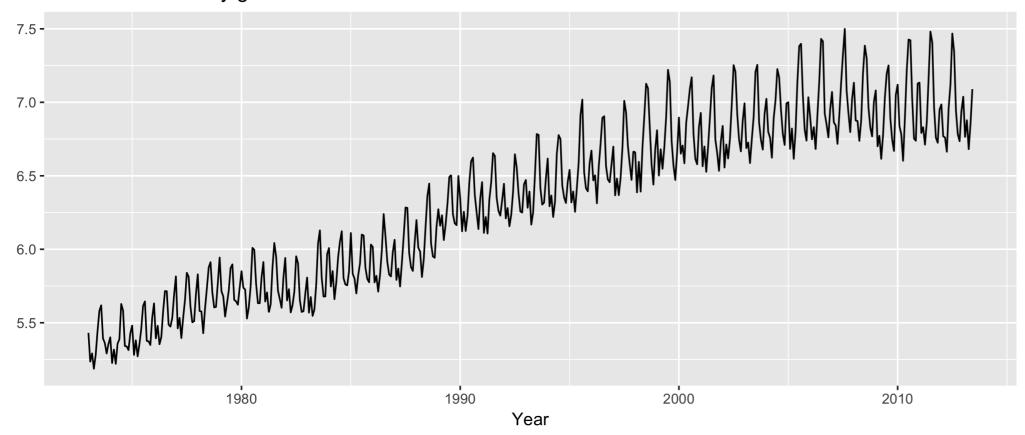

Square root electricity generation

```
autoplot(usmelec^0.33333) +
   xlab("Year") + ylab("") +
   ggtitle("Cube root electricity generation")
```

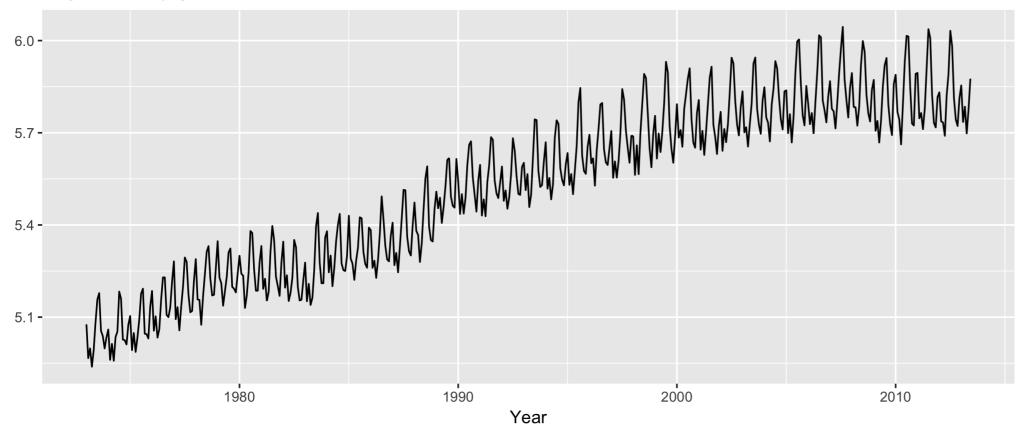

Cube root electricity generation

```
autoplot(log(usmelec)) +
  xlab("Year") + ylab("") +
  ggtitle("Log electricity generation")
```

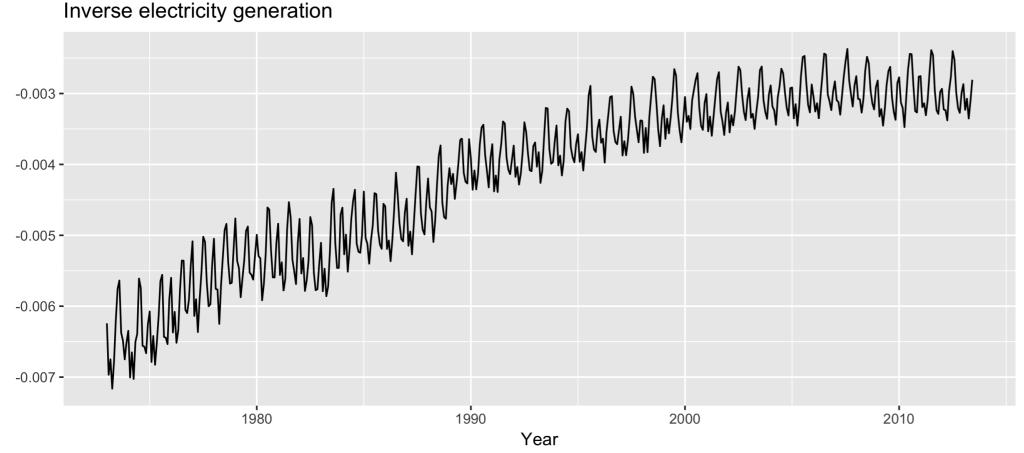

Log electricity generation

```
autoplot(-1/usmelec) +
 xlab("Year") + ylab("") +
  ggtitle("Inverse electricity generation")
```

Inverse electricity generation

Box-Cox transformations

 Each of these transformations is close to a member of the family of Box-Cox transformations

$$w_t = egin{cases} log(y_t) & \lambda = 0 \ (y_t^\lambda - 1)/\lambda & \lambda
eq 0 \end{cases}$$

- $\lambda=1$: No substantive transformation
- $\lambda=rac{1}{2}$: Square root plus linear transformation
- $\lambda = \frac{1}{3}$: Cube root plus linear transformation
- $oldsymbol{\cdot}$ $\lambda=0$: Natural logarithm transformation
- $\lambda = -1$: Inverse transformation

Box-Cox transformations

BoxCox.lambda(usmelec)

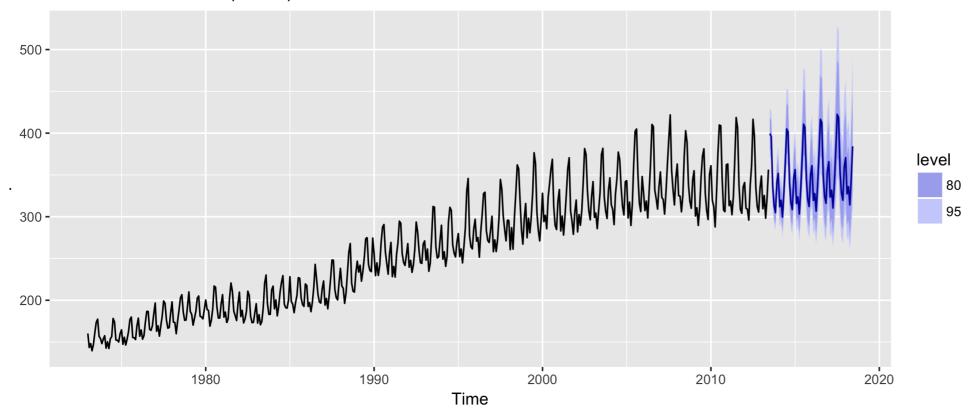

-0.5738331

Back-transformation

```
usmelec %>%
  ets(lambda = -0.57) %>%
  forecast(h = 60) %>%
  autoplot()
```

Forecasts from ETS(A,A,A)

FORECASTING IN R

FORECASTING IN R

Rob J. Hyndman

Professor of Statistics at Monash University

Autoregressive (AR) models:

- Multiple regression with lagged observations as predictors
- $y_t = c + \phi_1 y_{t-1} + \phi_2 y_{t-2} + ... + \phi_p y_{t-p} + e_t$

Moving average (MA) models:

- Multiple regression with lagged errors as predictors
- $y_t = c + \theta_1 e_{t-1} + \theta_2 e_{t-2} + \dots + \theta_q e_{t-q}$

Autoregressive moving average (ARMA) models:

Multiple regression with lagged observations and errors as predictors

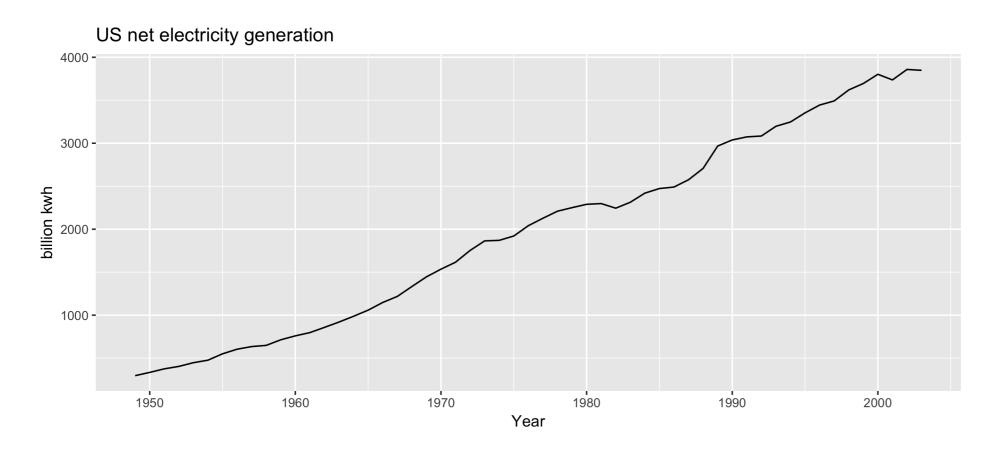

•
$$y_t = c + \phi_1 y_{t-1} + ... + \phi_p y_{t-p} + \theta_1 e_{t-1} + ... + \theta_q e_{t-q} + e_t$$

ARIMA(p, d, q) models:

Combine ARMA model with d - lots of differencing

US net electricity generation

```
autoplot(usnetelec) +
  xlab("Year") +
  ylab("billion kwh") +
  ggtitle("US net electricity generation")
```

US net electricity generation

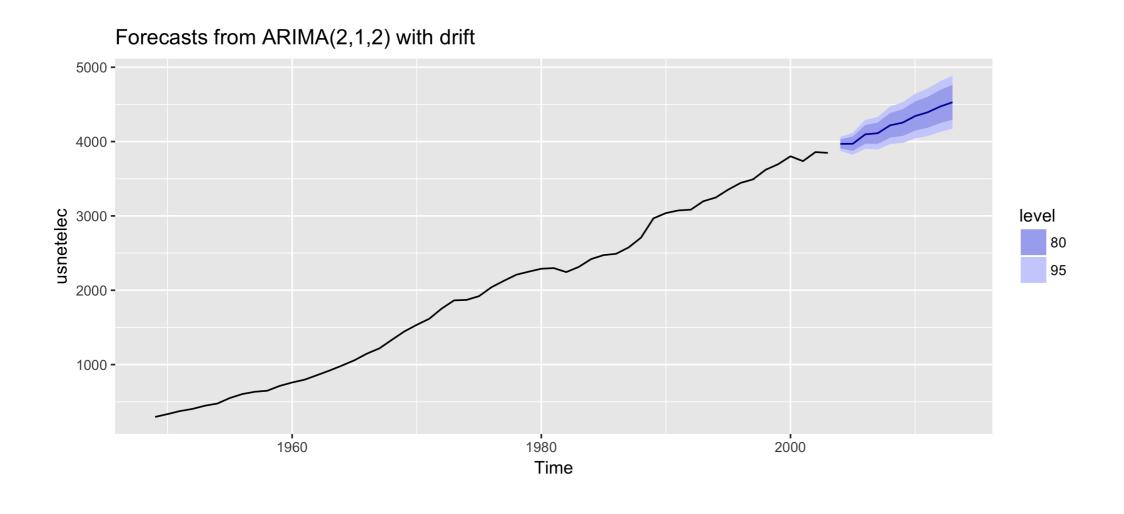

```
fit <- auto.arima(usnetelec)
summary(fit)</pre>
```

```
Series: usnetelec
ARIMA(2,1,2) with drift
Coefficients:
               ar2
                      ma1
                            ma2

```

US net electricity generation

fit %>% forecast() %>% autoplot()

How does auto.arima() work?

Hyndman-Khandakar algorithm:

- Select number of differences d via unit root tests
- ullet Select p and q by minimizing AIC_c
- Estimate parameters using maximum likelihood estimation
- Use stepwise search to traverse model space, to save time

Let's practice!

FORECASTING IN R

Seasonal ARIMA models

FORECASTING IN R

Rob J. Hyndman

Professor of Statistics at Monash University

ARIMA	(p, d, q)	(P, D, Q)m
	Non-seasonal part of the model	Seasonal part of the model

- d = Number of lag-1 differences
- p = Number of ordinary AR lags:
- q = Number of ordinary MA lags:

ARIMA	(p, d, q)	(P, D, Q)m
	Non-seasonal part of the model	Seasonal part of the model

- d = Number of lag-1 differences
- p = Number of ordinary AR lags:
- q = Number of ordinary MA lags:

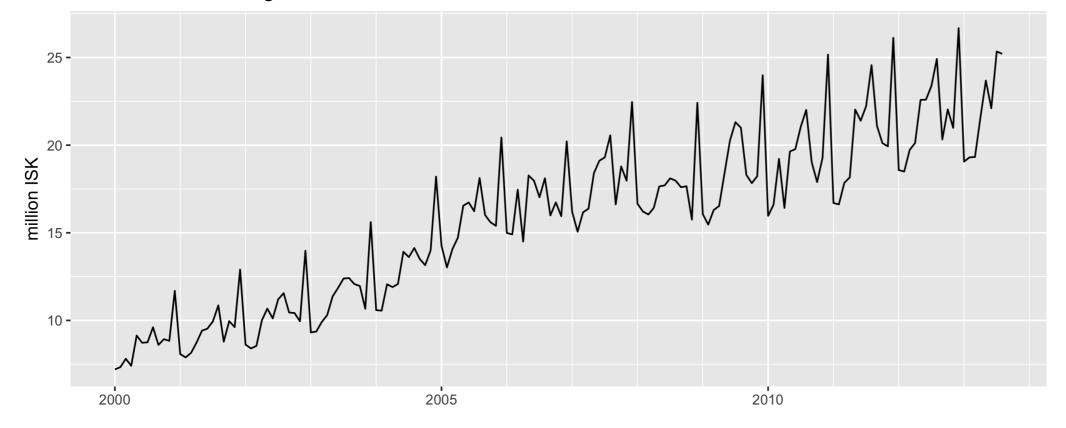

ARIMA	(p, d, q)	(P, D, Q)m
	· ·	Seasonal part of the
	the model	model

- d = Number of lag-1 differences
- p = Number of ordinary AR lags: $y_{t-1}, y_{t-2}, ..., y_{t-p}$
- q = Number of ordinary MA lags: $\epsilon_{t-1}, \epsilon_{t-2}, ..., \epsilon_{t-q}$
- D = Number of seasonal differences
- P = Number of seasonal AR lags: $y_{t-m}, y_{t-2m}, ..., y_{t-Pm}$
- Q = Number of seasonal MA lags: $\epsilon_{t-m}, \epsilon_{t-2m}, ..., \epsilon_{t-Qm}$
- m = Number of observations per year

Example: Monthly retail debit card usage in Iceland

```
autoplot(debitcards) +
  xlab("Year") + ylab("million ISK") +
  ggtitle("Retail debit card usage in Iceland")
```

Retail debit card usage in Iceland

Example: Monthly retail debit card usage in Iceland

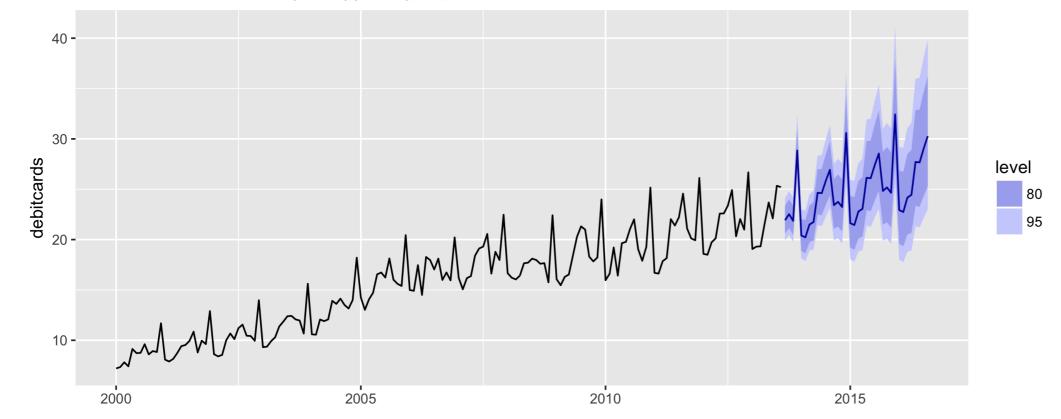

```
fit <- auto.arima(debitcards, lambda = 0)
fit</pre>
```

```
